

Define the Problem Statements

Auto-Ticket Classification using Flow Designer

Identifying the core helpdesk challenges

1. Problem Context

School IT helpdesk teams receive a high volume of support requests from students. These requests cover diverse issues such as Wi-Fi connectivity, hardware faults, password resets, and software performance. Without a structured classification system, each ticket must be manually triaged by a technician before work can begin.

2. Problem Statement

Students submitting IT support requests must manually select technical categories they may not understand. This leads to misclassification, delayed routing, and increased workload for the helpdesk team. There is no automated mechanism to classify tickets based on the issue description provided by the student.

3. Impact Analysis

Impact Area	Current State	Desired State
Ticket Accuracy	Frequent misclassification	Automatic keyword-based classification
Response Time	Delayed due to manual triage	Immediate classification on creation
Student Experience	Confusing category selection	Simple description-only submission
Technician Workload	Repetitive manual sorting	Pre-classified tickets ready for action

4. Target Outcome

- Students submit tickets using only a short description - no manual category selection.
- Flow Designer automatically classifies the ticket by detecting supported keywords.
- Category and Subcategory fields are populated without human intervention.
- An acknowledgment email is sent to the student immediately after submission.
